Problem 1

Proof. Let $V = \text{span}\{v_1, \dots, v_n\}$, where v_1, \dots, v_n are linearly independent elements in V . Then there exists n linearly independent elements $x_1, \dots, x_n \in X$ such that $T(x_i) = v_i, i = 1, \dots, n$. The existence promised by the fact that T is a linear operator. Let $Y_0 = \text{span}\{x_1, \dots, x_n\}$. Hence, $\dim(Y_0) = \dim(V) = n$.

Also, $\ker(T) \cap Y_0 = \{0\}$. Indeed, if $\exists y \neq 0, y \in Y_0$ such that $T(y) = 0$. Let $y = \sum_{i=1}^n \beta_i x_i$. Then there exists $\beta_i \neq 0$. By linearity of T , $T(y) = \sum_{i=1}^n \beta_i T(x_i) = \sum_{i=1}^n \beta_i v_i \neq 0$ and it yields a contradiction.

Next, we will show $\ker(T) + Y_0 = X$. Suppose not, for any $x \in X$, there exists $z \notin \ker(T) + Y_0, w \in \ker(T), r \in Y_0$ such that $x = z + w + r$. Let $r = \sum_{i=1}^n t_i x_i$, and $T(x) = \sum_{i=1}^n \alpha_i v_i$. Hence,

$$\sum_{i=1}^n \alpha_i v_i = T(x) = T(z) + T(w) + T(r) = T(z) + \sum_{i=1}^n t_i v_i.$$

, which implies that $T(z) = \sum_{i=1}^n (\alpha_i - t_i) v_i$.

However, $z \notin \ker(T) + Y_0$ and so $T(z) \notin \text{span}\{v_1, \dots, v_n\} \subset (\ker(T) + Y_0)$. Hence, it is a contradiction.

In conclusion, $\ker(T) + Y_0 = X$ and $\ker(T) \cap Y_0 = \{0\}$, and it implies that $X = \ker(T) \oplus Y_0$. \square

Problem 2

Proof. If T is continuous, then the preimage (i.e., $\ker(T)$) of $\{0\}$ is closed since $\{0\}$ is closed. Also, $\ker(T)$ is a subspace due to the linearity of T .

If $\ker(T)$ is a closed subspace in X , we need to show that T is continuous, or equivalently, bounded. Since Y is a finite-dimensional space, from the result of problem 1, we know there exists a finite-dimensional subspace $Y_0 \subset X$ such that $X = \ker(T) \oplus Y_0$. Hence, for any $x \in X$, there exists $y \in \ker(T), z \in Y_0$ such that $x = y + z$.

Also, from $X = \ker(T) \oplus Y_0$, $\dim(Y_0)$ is finite and $\ker(T)$ is closed, we know that both projection maps Π_{\ker} and Π_{Y_0} are bounded. $y = \Pi_{\ker}(x), z = \Pi_{Y_0}(x)$.

Consider the norm of T . For any $x \in X$, by linearity, $T(x) = T(y) + T(z) = T(z) = T \circ \Pi_{Y_0}(x)$.

$$\|T\|_\infty = \sup_{x \in X \setminus \{0\}} \frac{\|T(x)\|_Y}{\|x\|_X} = \sup_{x \in X \setminus \{0\}} \frac{\|T \circ \Pi_{Y_0}(x)\|_Y}{\|\Pi_{Y_0}(x)\|_X} \frac{\|\Pi_{Y_0}(x)\|_X}{\|x\|_X}$$

Since Π_{Y_0} is bounded, $\frac{\|\Pi_{Y_0}(x)\|_X}{\|x\|_X} < +\infty$ for any $x \in X \setminus \{0\}$. Consider linear operator $T|_{Y_0} : Y_0 \rightarrow Y$ and it is bounded since $\dim(Y_0) < +\infty$.

$$\sup_{x \in X \setminus \{0\}} \frac{\|T \circ \Pi_{Y_0}(x)\|_Y}{\|\Pi_{Y_0}(x)\|_X} \leq \sup_{y \in Y_0 \setminus \{0\}} \frac{\|T|_{Y_0}(y)\|_Y}{\|y\|_X} < +\infty.$$

Hence, $\|T\|_\infty < +\infty$ and so T is continuous. □

Problem 3

Proof. Denote the graph of f as $G(f) := \{(x, f(x)) | x \in X\} \subset X \times Y$. Let $\{z_n\}_{n \in \mathbb{N}} = \{(x_n, f(x_n))\}_{n \in \mathbb{N}} \subset G(f)$ that converges to $z = (x, y)$. It is enough to show that $y = f(x)$.

Indeed, $x = \lim_{n \rightarrow +\infty} x_n$ and so $\lim_{n \rightarrow +\infty} f(x_n) = f(x)$ due to the continuity of f . Also, $y = \lim_{n \rightarrow +\infty} f(x_n)$. Hence, $y = f(x)$. □

Question: Here we only need X, Y to be metric spaces. We didn't really need completeness. Is it correct?

Problem 4

(a) *Proof.* Prove by contradiction.

Suppose that f is not continuous on \mathbb{R} . Hence, there exists one sequence $\{x_n\}_{n \in \mathbb{N}} \subset \mathbb{R}$ that converges to x , such that a subsequence $\{x_{n_k}\}_{k \geq 1} \subset \{x_n\}_{n \geq 1}$, from which $\{f(x_{n_k})\}$ doesn't converge to $f(x)$.

Since f is bounded, we know that $\{f(x_{n_k})\}$ must have a convergent subsequence, denote as $\{f(x_{n_{k_l}})\}_{l \geq 1} \rightarrow y$. Also, we know $\{x_{n_{k_l}}\} \rightarrow x$ and with closeness of $G(f)$, we know $y = f(x)$. This is equivalent to say that $\{f(x_{n_{k_l}})\}_{l \geq 1} \rightarrow f(x)$. It leads to a contradiction to the assumption that $\{f(x_{n_k})\}$ doesn't converge to $f(x)$.

In conclusion, f is a continuous function. □

(b) Let f be the following function,

$$f(x) = \begin{cases} \frac{1}{x} & x \neq 0 \\ 0 & x = 0. \end{cases}$$

Problem 5

Proof. \Rightarrow If T_1 is compact and T_2 is continuous, then, for any bounded sequence $\{x_n\}_{n \in \mathbb{N}} \subset X$, there exists a subsequence $\{x_{n_k}\} \subset \{x_n\}$ such that $\{y_{n_k}\} := \{T_1(x_{n_k})\}$ converges in Y . Denote $\lim_{k \rightarrow +\infty} y_{n_k} = y$. Since T_2 is continuous, $T_2(y_{n_k}) \rightarrow T_2(y) \in Z$. i.e., for any bounded sequence $\{x_n\}_{n \in \mathbb{N}} \subset X$, there exists a subsequence $\{x_{n_k}\} \subset \{x_n\}$ such that $\{T_2 \circ T_1(x_{n_k})\}$ converges in Z . In conclusion, $T_2 \circ T_1$ is compact.

\Leftarrow Conversely, suppose T_2 is compact and T_1 is continuous. Then, for any bounded set $U \in X$, $T_1(U) = V$ is also a bounded set in Y since T_1 is bounded. By compactness, $\overline{T_2(V)}$ is compact. Hence, for any bounded set $U \in X$, $T_2 \circ T_1(U)$ is compact in Z . Hence, $T_2 \circ T_1$ is compact. □

Problem 6

(i) *Proof.* T is linear, bounded and bijective so that T^{-1} exists and bounded. Note that $\|x\| = \|T^{-1} \circ T(x)\|$. Hence, there exists $M > 0$, such that

$$\frac{\|x\|}{\|T(x)\|} = \frac{\|T^{-1} \circ T(x)\|}{\|T(x)\|} \leq \sup_{y \in X \setminus \{0\}} \frac{\|T^{-1}(y)\|}{\|y\|} \leq M.$$

Let $\beta = 1/M$, then $\|T(x)\| \geq \beta\|x\|, \forall x \in X$. □

(ii) *Proof.* From (i) we know that T^{-1} exists as a linear bounded operator. $\|T^{-1}\| \leq M = 1/\beta$.

For each $y \in Y$, we define a map $Q_y : X \rightarrow X$ such that $Q_y(x) := T^{-1}(y - \Psi(x))$, where Ψ is a bounded linear operator with norm $\|\Psi\|_\infty < \beta$. It is enough to show that Q_y is a contraction mapping.

Indeed, for any $x_1, x_2 \in X$, we have

$$\begin{aligned} \|Q_y(x_1) - Q_y(x_2)\| &= \|T^{-1}(y - \Psi(x_1)) - T^{-1}(y - \Psi(x_2))\| \leq \|T^{-1}\|_\infty \|y - \Psi(x_1) - (y - \Psi(x_2))\| \\ &= \|T^{-1}\|_\infty \|\Psi(x_1) - \Psi(x_2)\| \\ &\leq \|T^{-1}\|_\infty \|\Psi\|_\infty \|x_1 - x_2\| \\ &= c\|x_1 - x_2\|. \end{aligned}$$

where $c = \|T^{-1}\|_\infty \|\Psi\|_\infty \in (0, 1)$. This yields that Q_y is a contraction mapping for each $y \in Y$.

Hence, equation $x = Q_y(x)$ has a unique solution for each $y \in Y$. □
