# Multiplicative Weights (MW) Algorithm Overview

- A decision maker has a set of *n* possible decisions
- Begin with equal probabilities of choosing each decision
- In each iteration:
  - 1 Decision maker chooses a decision
  - 2 Obtains a (possibly negative) payoff
  - 3 Adjusts the probabilites with a multiplicative factor based on payoff

- t: iteration number (aka "round")
- T: Number of iterations in total.
- $p^{(t)} \in \mathbb{R}^n$ : probability vector for round t $p_i^{(t)}$  is the probability of selecting decision i in round t
- $m^{(t)} \in \mathbb{R}^n$ : gain vector "revealed by nature" after the decision in round t is made (assume  $m_i^{(t)} \in [-1,1], \ \forall i, \ \forall t$ )

### General MW Algorithm

Fix  $\eta \leq \frac{1}{2}$ . Initialize  $w_i^{(0)} = 1$ ,  $\forall i = 1, ..., n$ .

For t = 1, ..., T:

- **1** Choose decision *i* with probability  $p_i^{(t)} = \frac{w_i^{(t)}}{\sum_i w_i^{(t)}}$
- 2 Observe the payoff  $m^{(t)}$
- $\odot$  Update the weights: for each i,

$$w_i^{(t+1)} = w_i^{(t)} \exp(\eta m_i^{(t)})$$

#### Performance

 Expected gain is "not too much less" than the gain of the best decisions

$$\sum_{t=1}^{T} m^{(t)} \cdot p^{(t)} \ge \sum_{t=1}^{T} m_{i}^{(t)} - \eta \sum_{t=1}^{T} (m_{i}^{(t)})^{2} \cdot p^{(t)} - \frac{\ln n}{\eta}$$

$$(\forall i = 1, \ldots, n).$$

 MW has many applications in machine learning, game theory, online decision making, etc.

#### Linear Classifier Problem

MW algorithm can be used to solve a linear classifier problem

- *m* labeled examples  $(\ell_i, a_i)$ , with  $\ell_i \in \{-1, 1\}$  and  $a_i \in \mathbb{R}^n$
- Want to find a normal vector x to a hyperplane so that

$$\operatorname{sgn}(a_j^T x) = \ell_j \quad \forall j = 1, \dots, m$$

Equivalently, we want to find x such that

$$\ell_j a_j^T x \ge 0 \quad \forall j = 1, \dots, m$$

(Redefine  $a_j \rightarrow \ell_j a_j$ )

MW for SDP

### MW Algorithm to Solve an LP

MW Algorithm can be used to solve the following LP:

$$a_j^T x \ge 0$$
  $\forall j = 1, ..., m$   
 $\mathbb{1}^T x = 1$   
 $x_i \ge 0$   $\forall i = 1, ..., n$ 

(x is analogous to the distribution p)

# MW Algorithm to Solve the Linear Classifier Problem

Define  $\rho = \max_j ||a_j||_{\infty}$ ,  $\eta = \frac{\epsilon}{2\rho}$ ,  $\epsilon > 0$ .

Initialize 
$$x_i^{(0)} = \frac{1}{n}, \forall i$$

While  $\exists j \text{ s.t. } a_i^T x^{(t)} < 0$ 

- **1** Find the index j such that  $a_i^T x^{(t)} < 0$
- **2** Obtain payoff  $m^{(t)} = \frac{a_j}{\rho}$
- 3 Update  $x^{(t)}$ : for each i,

$$x_i^{(t+1)} = x_i^{(t)} \exp(\eta m_i^{(t)})$$

Algorithm Overview

MW for LP

MW for SDP

Solving an SDP using Multiplicative Weights algorithm:

Recall the LP:

$$a_j^T x \ge 0 \quad \forall j$$

$$\mathbb{1}^T x = 1$$

$$x_i \ge 0 \quad \forall i$$

Now the SDP:

$$A_j \bullet X \ge 0 \quad \forall j = 1, \dots, m$$

$$Tr(X) = 1$$

$$X \in \mathbb{S}^n_+$$

Gao, Gaddy

Algorithm Overview

MW for LP

MW for SDP

### Matrix MW Algorithm

Define  $\rho = \max_{j} ||A_{j}||, \ \eta = -\ln(1 - \epsilon), \epsilon > 0.$ 

Initialize 
$$W^{(0)} = I_n$$
 and  $X^{(0)} = W^{(0)} / Tr(W^{(0)})$ .

While  $\exists j \text{ s.t. } A_j \bullet X^{(t)} < 0$ :

- **1** Find the index j such that  $A_j \bullet X^{(t)} < 0$
- 2 Obtain the payoff  $M^{(t)} = \frac{A_j}{\rho}$
- **3** Update the weight matrix  $W^{(t)}$  and  $X^{(t)}$ :

$$W^{(t+1)} = \exp\left(\eta \sum_{\tau=1}^{t} M^{(\tau)}\right)$$
$$X^{(t+1)} = \frac{W^{(t+1)}}{Tr(W^{(t+1)})}$$

### Recall the MAXCUT problem

Given a weighted graph G = (E, V), find a partition of the vertices into two vertex sets  $V_1$  and  $V_2$ , i.e.,  $V = V_1 \cup V_2$ , that maximizes the "cut" edge weights.

(pic of graph)

Gao, Gaddy

Algorithm Overview

MW for LP

MW for SDP

### Recall the MAXCUT problem

For a graph G = (E, V) with |V| = n and  $V = V_1 \cup V_2$ , the vector  $x \in \mathbb{R}^n$  gives the partition:

$$x_i = \begin{cases} 1, & \text{if } v_i \in V_1 \\ -1, & \text{if } v_i \in V_2 \end{cases} \quad i = 1, \dots, n$$

Let  $w_{ij} := \text{the weight on edge } (i, j)$ 

$$\max_{x \in \{-1,1\}^n} \sum_{(i,j) \in E} w_{ij} \frac{1 - x_i x_j}{2}$$

#### The MAXCUT relaxation

Algorithm

Overview

MW for LP

MW for SDP

Introduce the auxiliary matrix variable  $X = xx^T$ :

$$\max_{x,X} \sum_{(i,j)\in E} w_{ij} \frac{1 - x_i x_j}{2}$$
s.t.  $X = xx^T$ 

$$x_i^2 = 1$$

Then drop the rank 1 constraint for the relaxation:

$$\max_{X} \frac{1}{4} L \bullet X$$
s.t.  $X_{ii} = 1 \quad \forall i = 1 \dots, n$ 

$$X \ge 0$$

$$L_{ij} = \begin{cases} \sum_{k \in V} w_{ik}, & i = j \\ -w_{ij}, & i \neq j \end{cases}$$

Gao, Gaddy

MW for SDP

# Reformulating the MAXCUT relaxation

Decision form: Does there exist a b such that

$$\frac{1}{4}L \bullet X \ge b$$

$$X_{ii} = 1 \quad \forall i = 1 \dots, n$$

$$X \ge 0$$

Observe that  $X_{ii} = 1 \implies (e_i e_i^T) \bullet X = 1$ . Rescale X by  $\frac{1}{n}$ . Arrive at the formulation:

$$\left(\frac{n}{4b}L - I\right) \bullet X \ge 0$$

$$\left(n(e_i e_i^T) - I\right) \bullet X \ge 0 \quad \forall i = 1, \dots, n$$

$$\mathsf{Tr}(X) = 1$$

$$X \ge 0$$

Gao, Gaddy

MW for LP

MW for SDP

# Reformulating the MAXCUT relaxation

Let 
$$A_j = n(e_j e_i^T) - I$$
,  $j = 1, ..., n$  and  $A_{n+1} = \frac{n}{4b}L - I$ .

$$A_j \bullet X \ge 0 \quad \forall \ j = 1, \dots, n$$
 $A_{n+1} \bullet X \ge 0$ 
 $Tr(X) = 1$ 
 $X \ge 0$

# Matrix MW algorithm for MAXCUT (Large-Margin)

Define  $\rho = \max_{i} ||A_{i}||$ ,  $\eta = -\ln(1 - \epsilon)$ ,  $\epsilon > 0$ ,  $\delta > 0$ .

Initialize 
$$W^{(0)} = I_n$$
 and  $X^{(0)} = W^{(0)}/Tr(W^{(0)})$ .

While  $\exists j \text{ s.t. } A_i \bullet X^{(t)} < -\delta$ :

- **1** Find the index j such that  $A_j \cdot X^{(t)} < -\delta$
- 2 Obtain the payoff  $M^{(t)} = \frac{A_j}{\rho}$
- 3 Update the weight matrix  $W^{(t)}$  and  $X^{(t)}$ :

$$W^{(t+1)} = \exp\left(\eta \sum_{\tau=1}^{t} M^{(\tau)}\right), \quad X^{(t+1)} = \frac{W^{(t+1)}}{Tr(W^{(t+1)})}$$

MW for SDP

#### Conclusions

- The MW algorithm can be used to solve LP and SDP feasibility problems of certain form.
- Use the MW algorithm to solve Linear Classification problems.
- Matrix MW algorithm performance depends on  $\epsilon$  and  $\delta$ . (Parameter sensitive).
